Machine Learning for Jets Activity

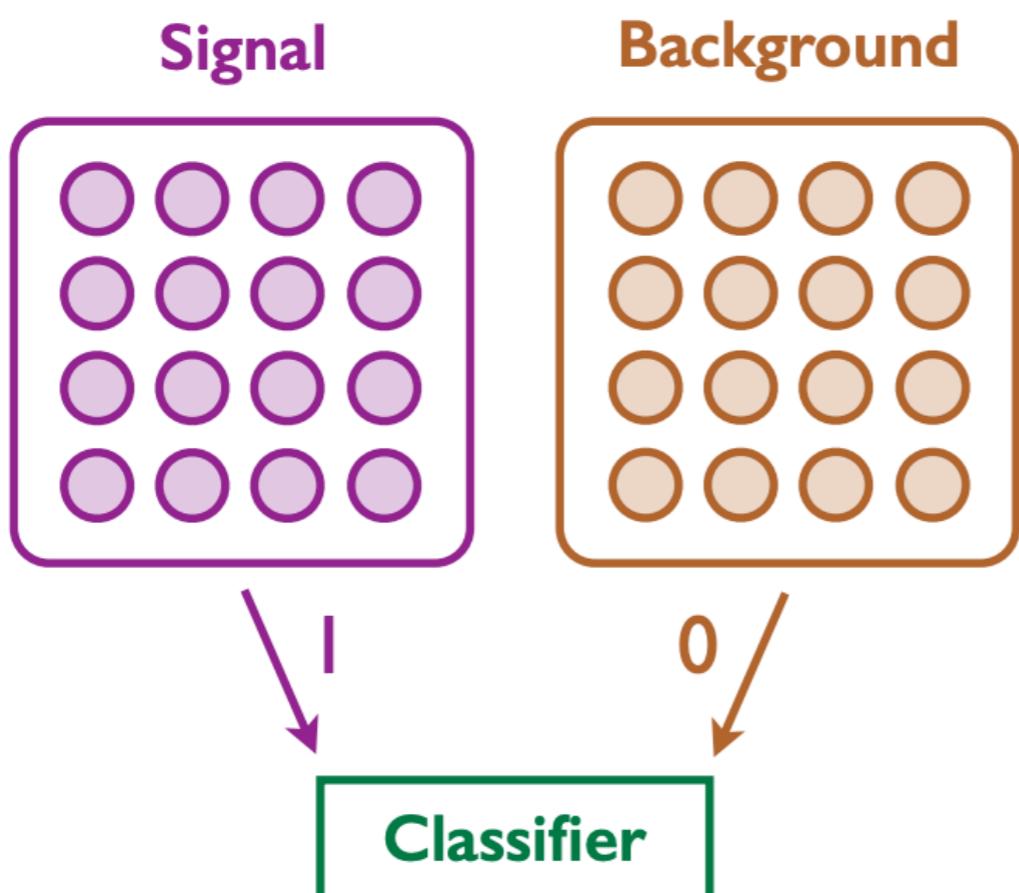

[Nachman, Boost 2018 Talk, July 18, 2018]

A Cartoon of Machine Learning

For fully-supervised jet classification

$$\ell_{\text{MSE}} = \left\langle (\textcolor{teal}{h}(\vec{x}) - 1)^2 \right\rangle_{\text{signal}} + \left\langle (\textcolor{teal}{h}(\vec{x}) - 0)^2 \right\rangle_{\text{background}}$$

Classifier Inputs

Minimize Loss Function

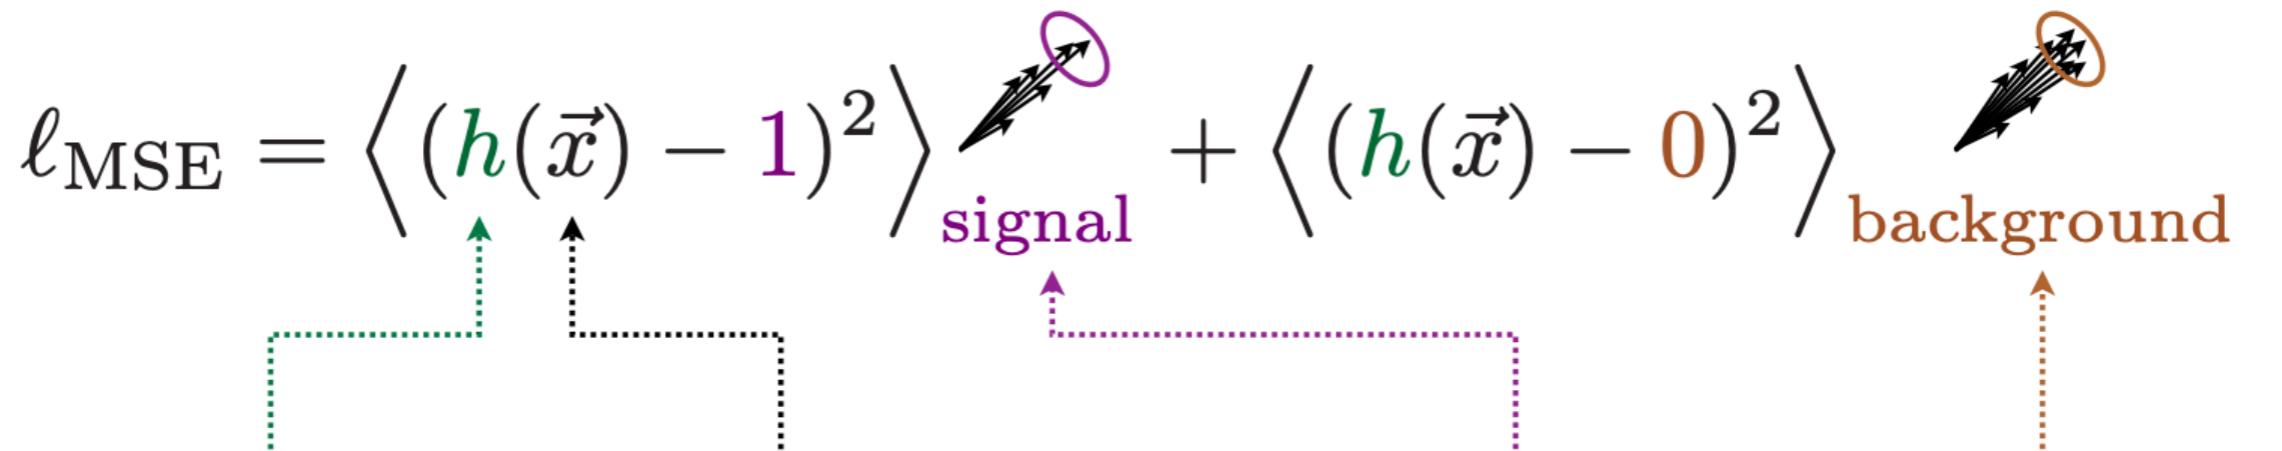

(assuming infinite training sets,
and flexible enough functional form)

$$h(\vec{x}) = \frac{p_{\text{sig}}(\vec{x})}{p_{\text{sig}}(\vec{x}) + p_{\text{bkgd}}(\vec{x})}$$

Optimal Classifier (Neyman–Pearson)

Jet Classification Studies

Mix and match

$$\ell_{\text{MSE}} = \left\langle (\mathbf{h}(\vec{x}) - 1)^2 \right\rangle_{\text{signal}} + \left\langle (\mathbf{h}(\vec{x}) - 0)^2 \right\rangle_{\text{background}}$$

Energy Flow Networks

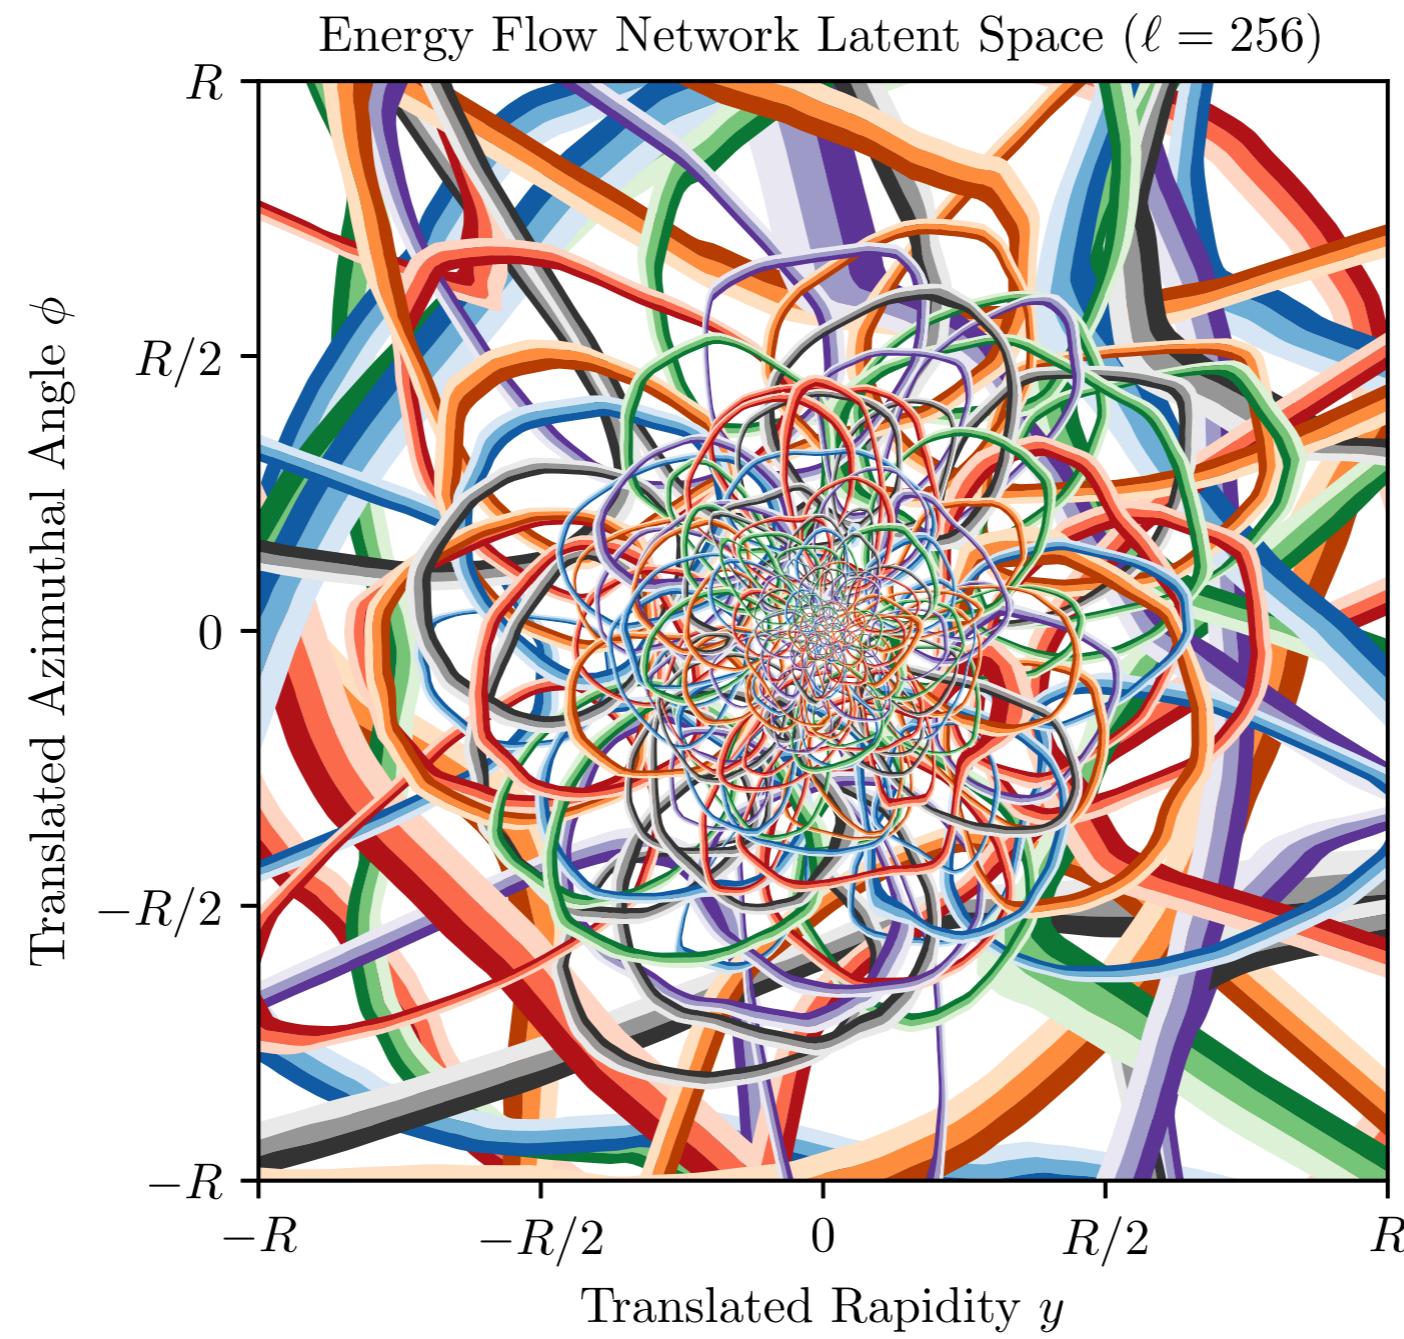

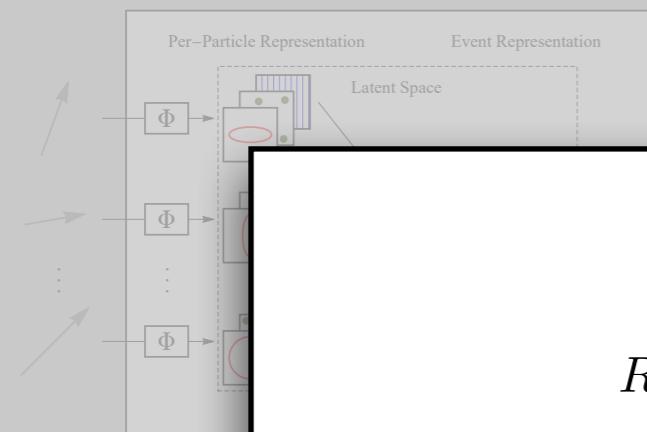

Energy Flow Moments

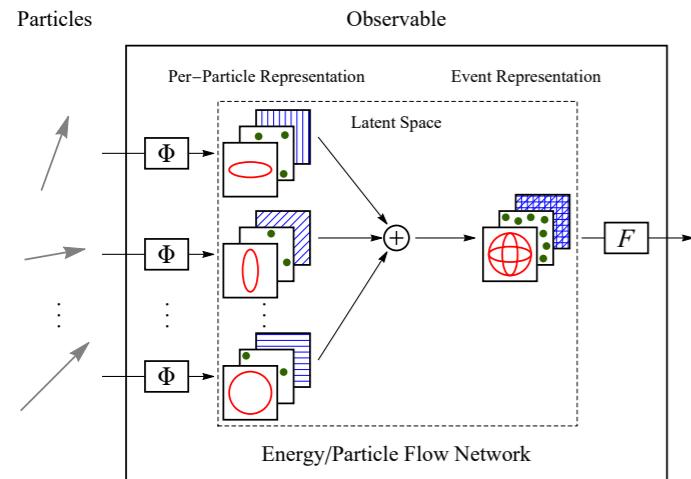

Energy Flow Polynomials

Particles

Observable

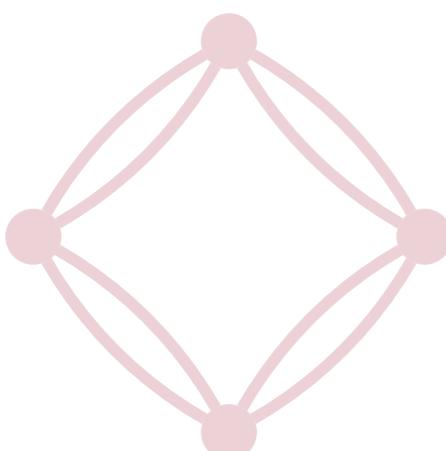

Energy Flow Networks

Energy Flow Moments

Energy Flow Polynomials

What is a Jet?

An **unordered, variable length collection of particles**

Due to quantum-mechanical indistinguishability
Due to probabilistic nature of jet formation

$$J(\{p_1^\mu, \dots, p_M^\mu\}) = J(\{p_{\pi(1)}^\mu, \dots, p_{\pi(M)}^\mu\}), \quad \underbrace{M \geq 1}_{\text{Multiplicity}}, \quad \underbrace{\forall \pi \in S_M}_{\text{Permutations}}$$

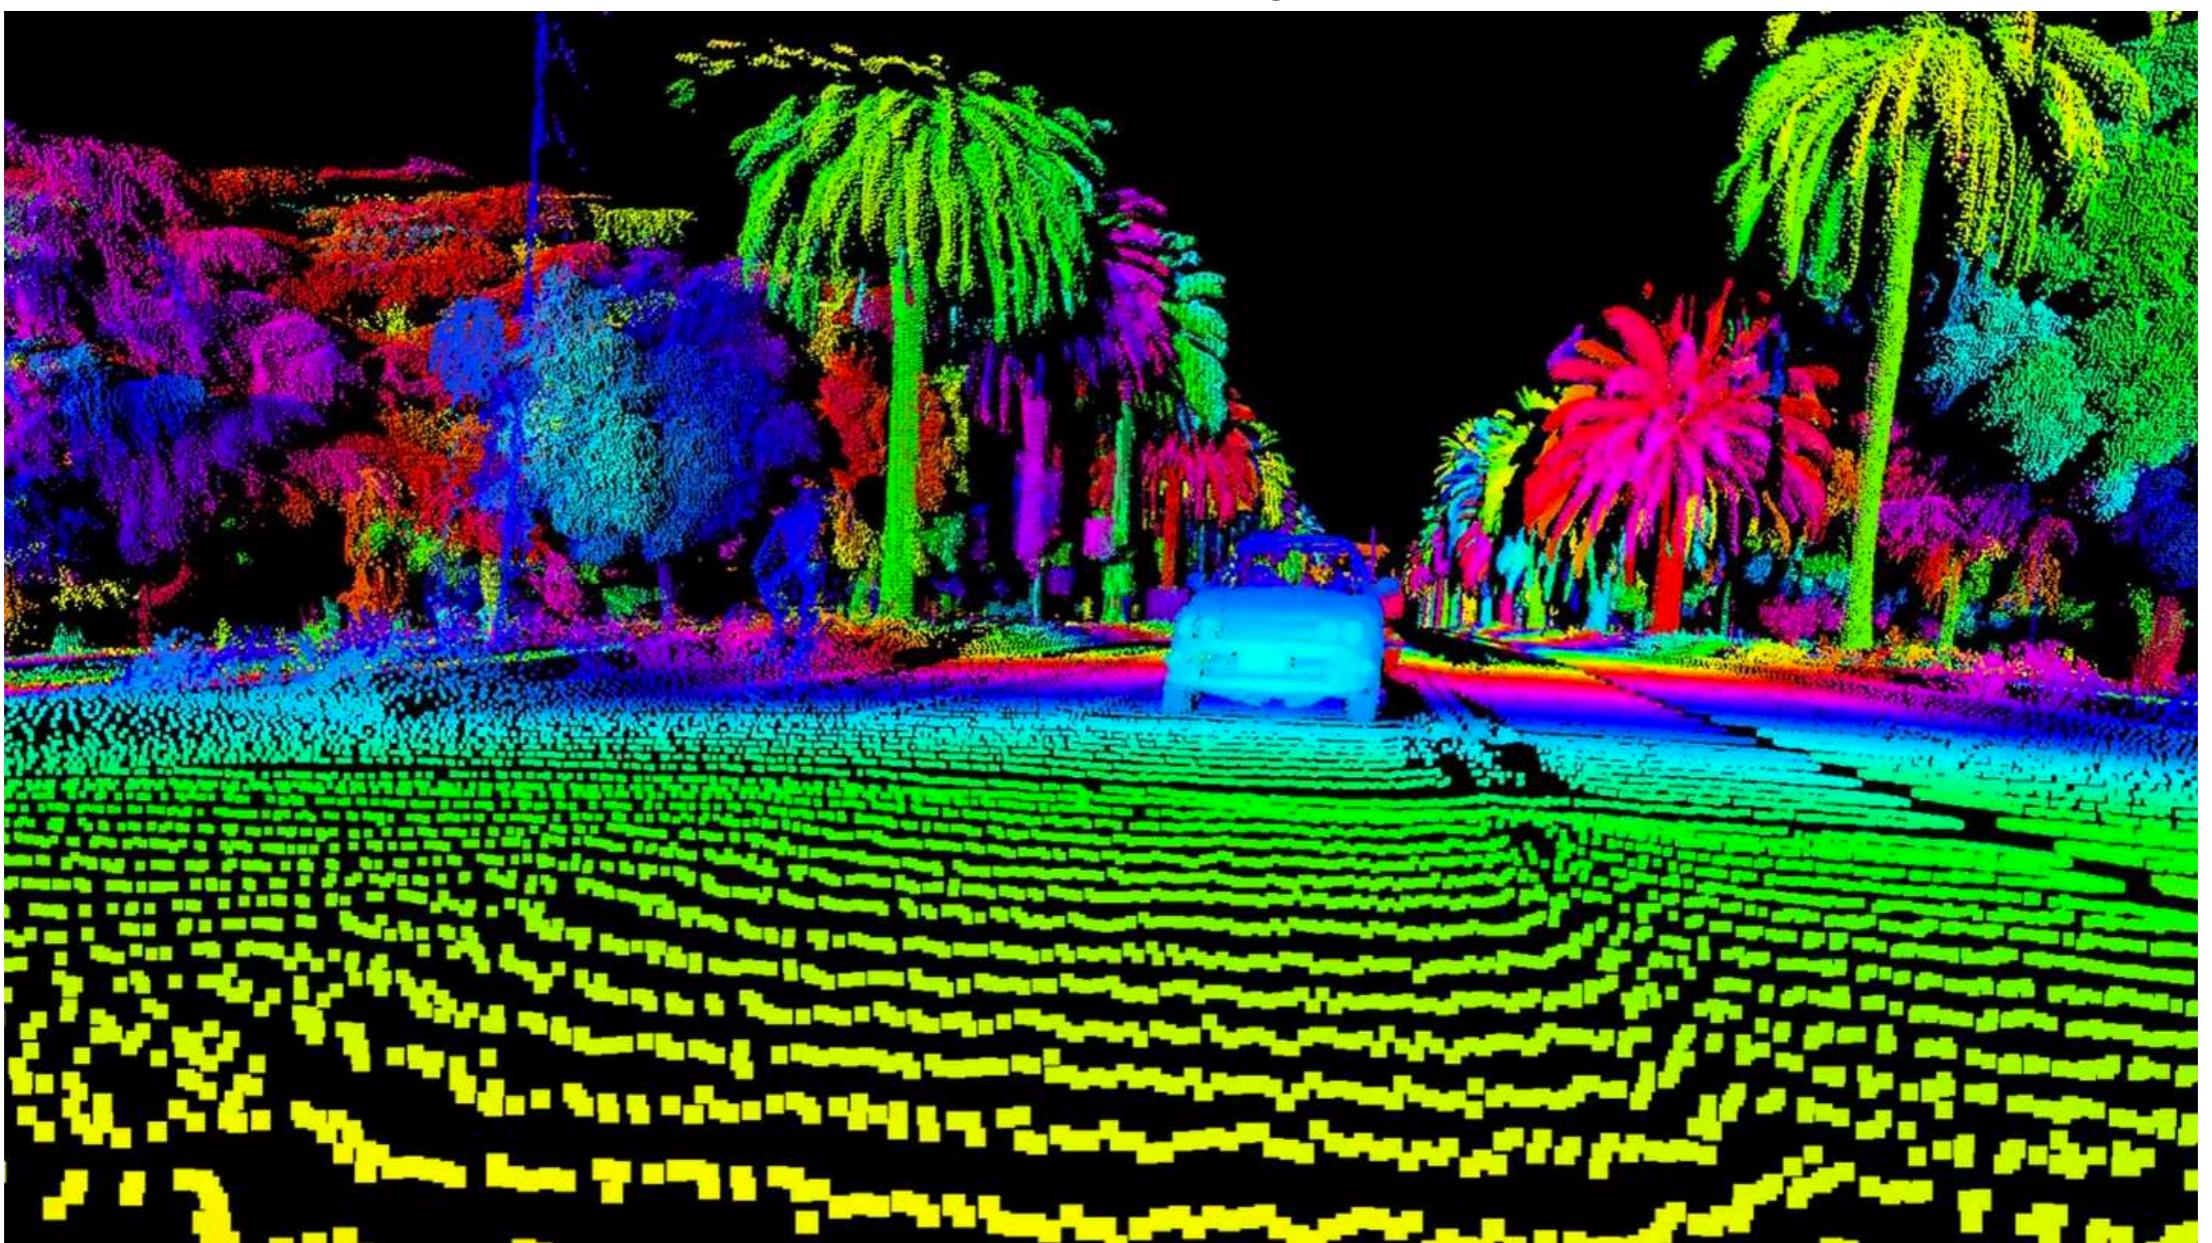

p_i^μ represents *all* the particle properties:

- Four-momentum – $(E, p_x, p_y, p_z)_i^\mu$
- Other quantum numbers (e.g. particle id, charge)
- Experimental information (e.g. vertex info, quality criteria, PUPPI weights)

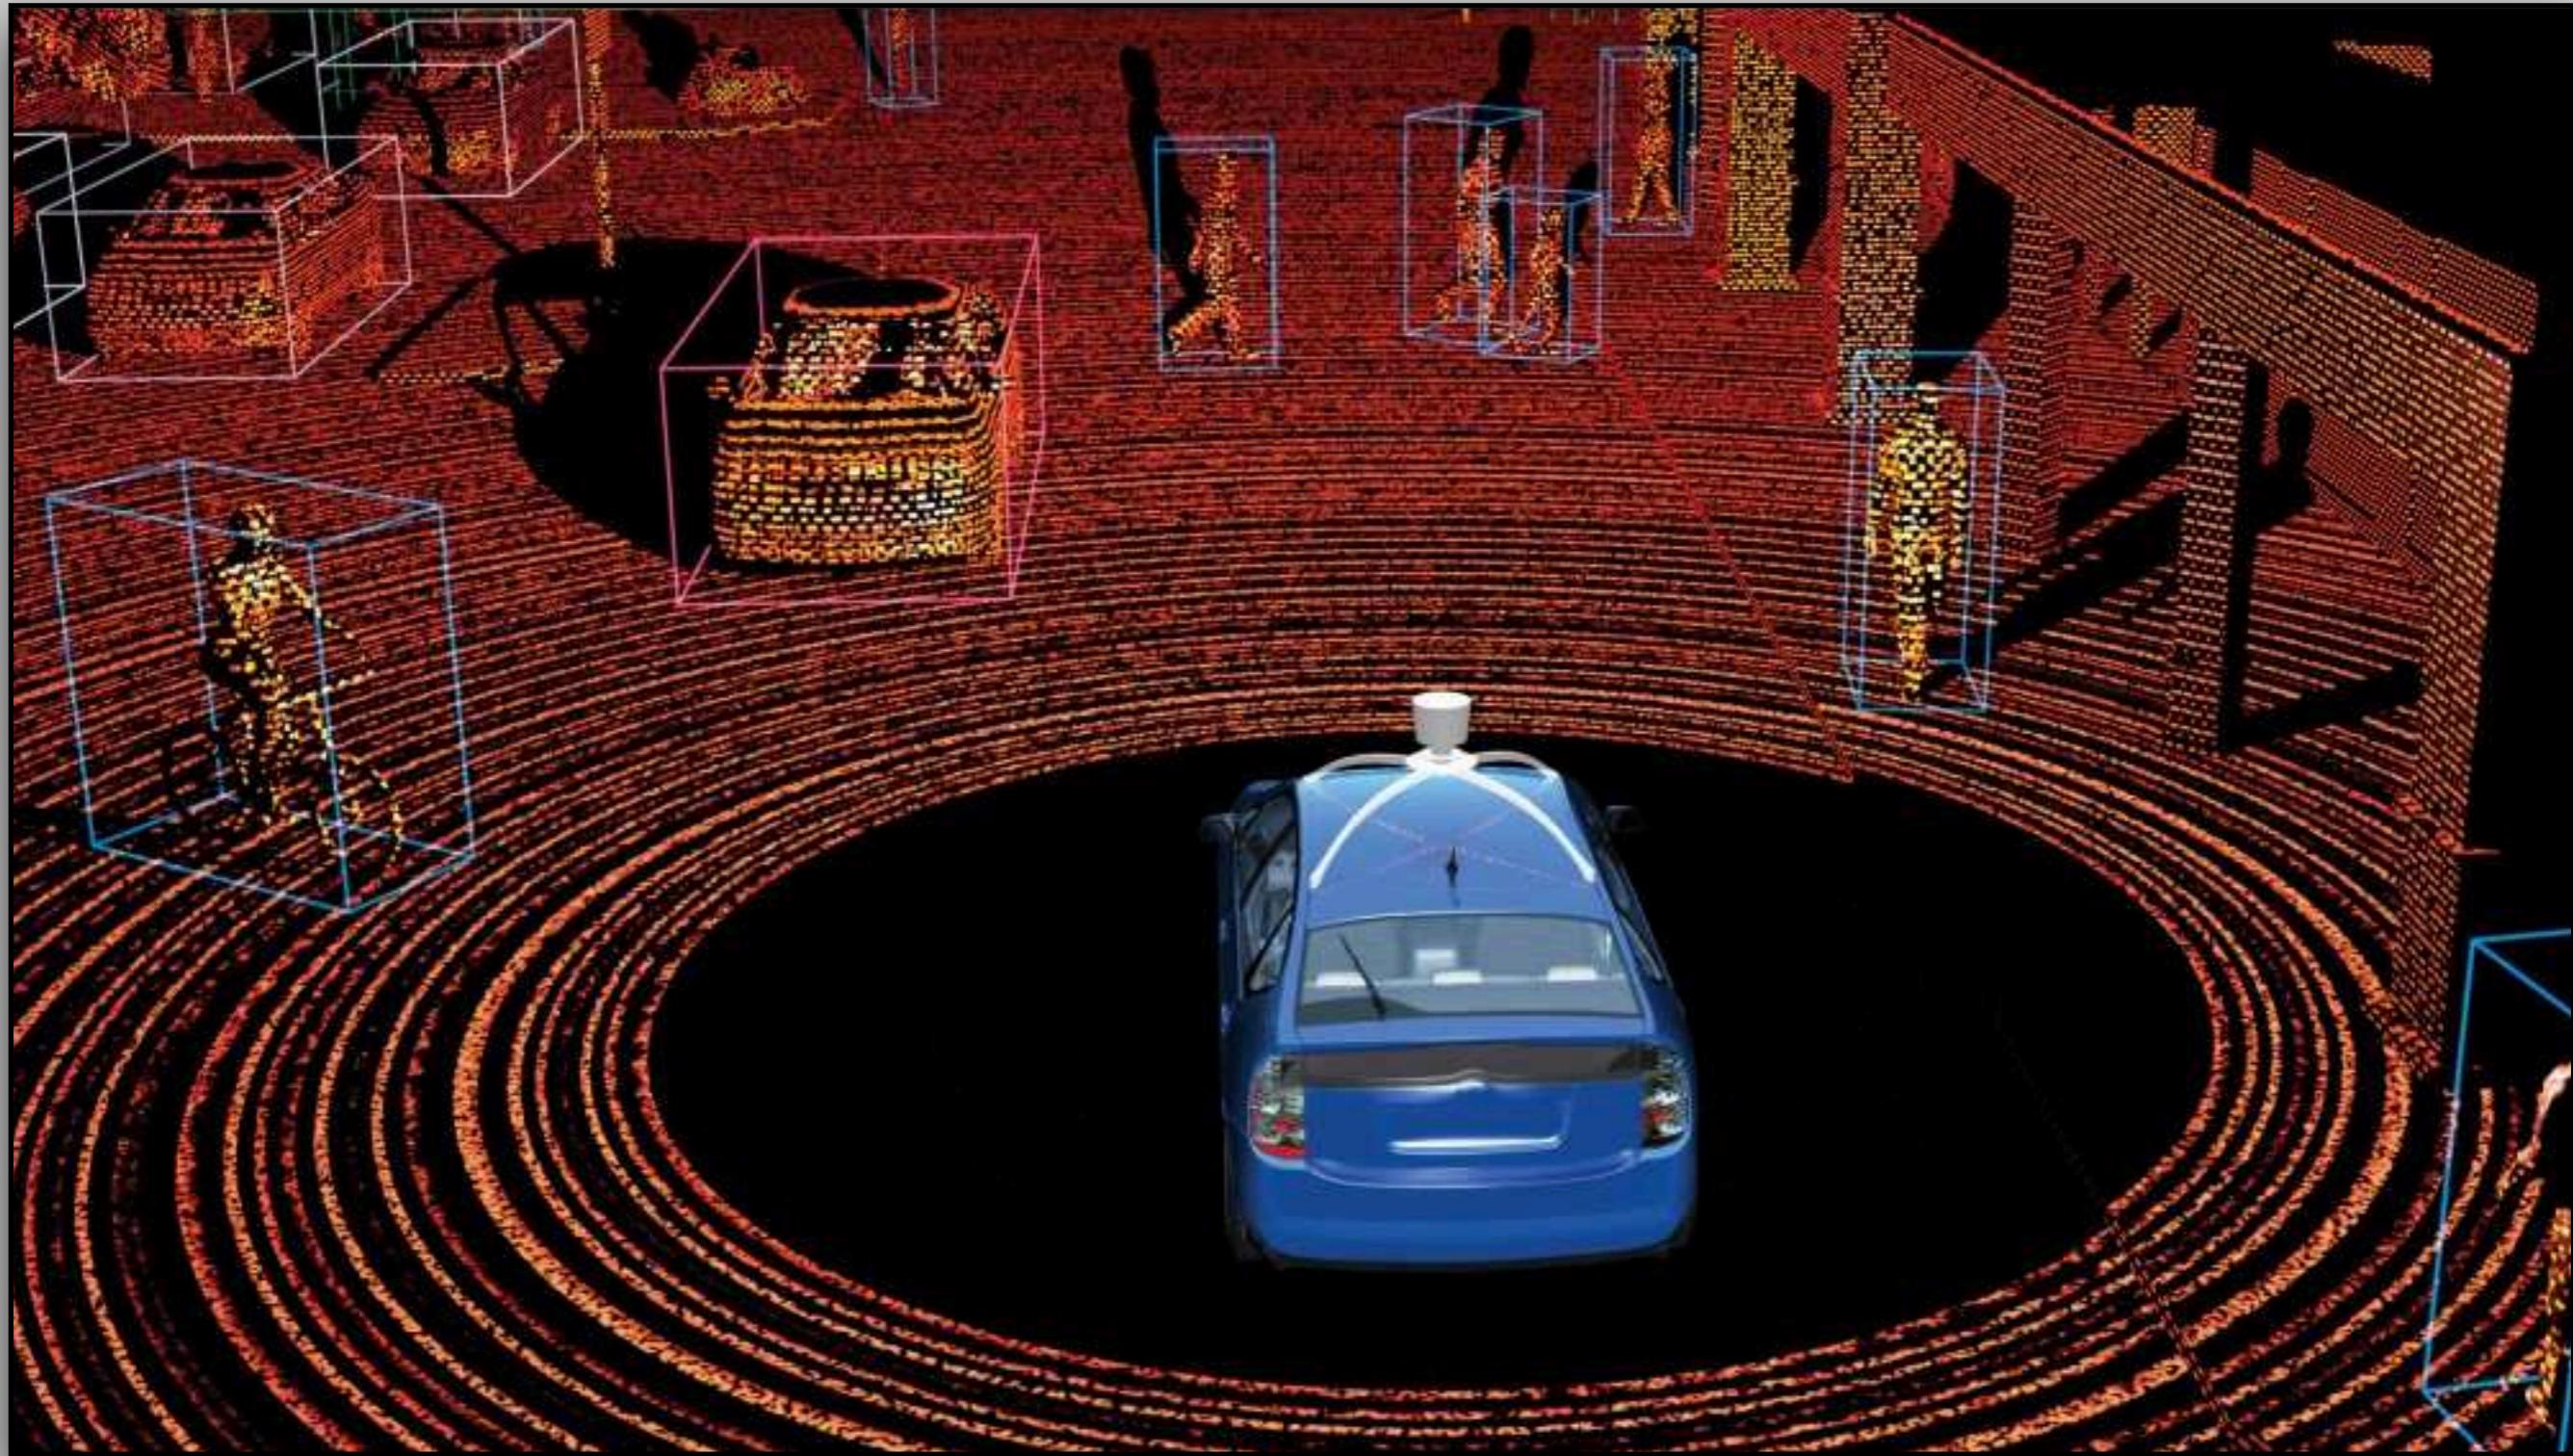

Point Clouds

Point cloud: "A set of data points in space" –Wikipedia

LIDAR data from self-driving car sensor

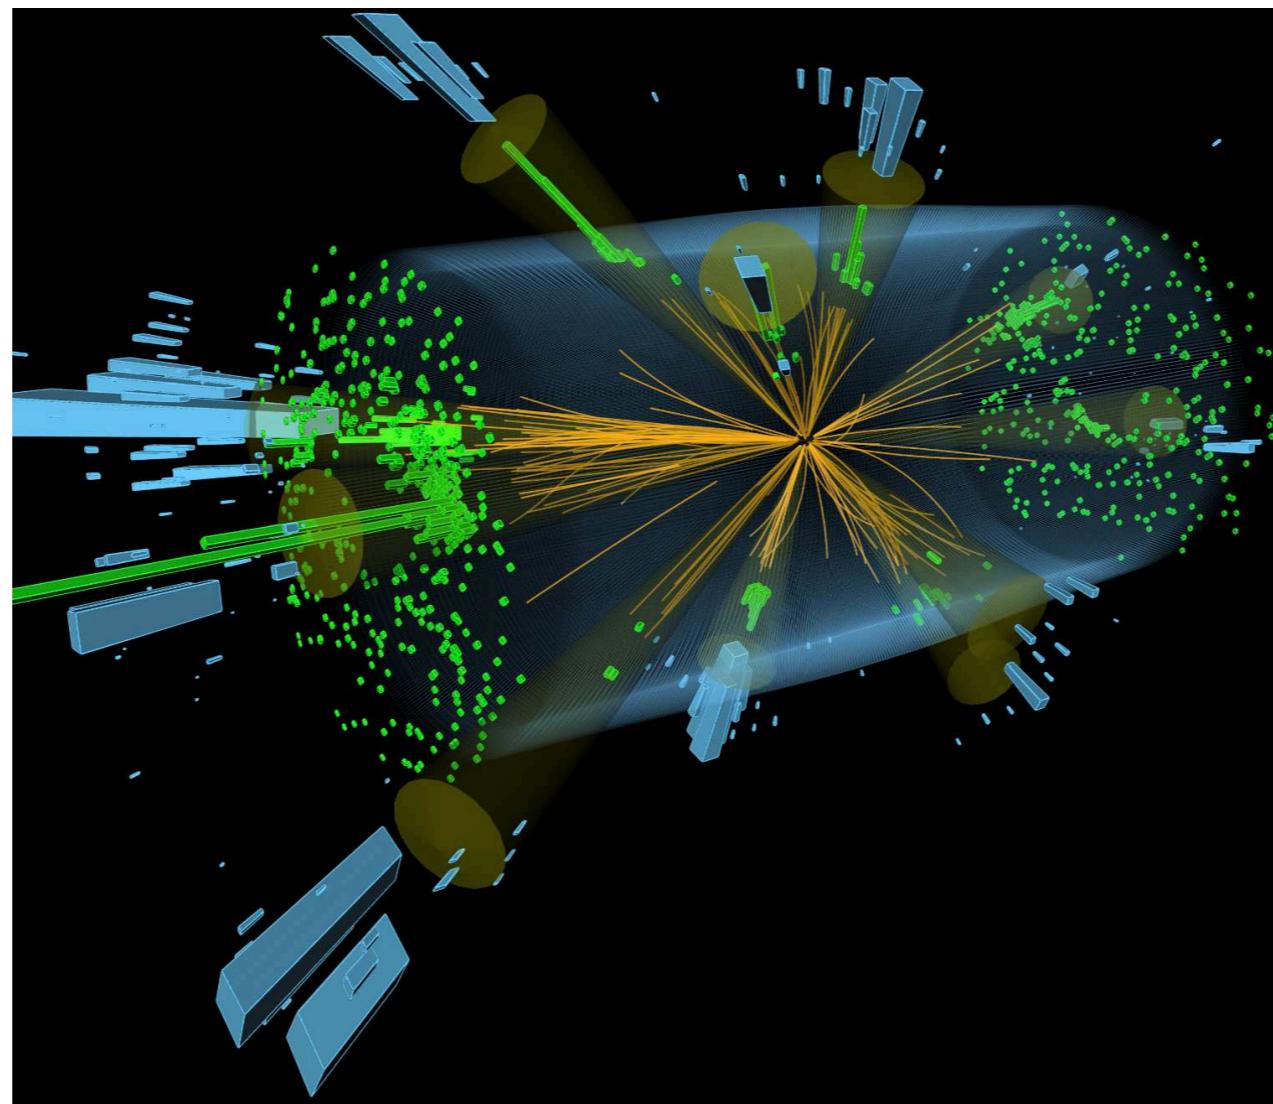

Point Clouds

Particle Collision Events as Point Clouds

Point cloud: "A set of data points in space" –Wikipedia

Jet/event Particles Feature space

Multi-jet event at CMS

Processing Point Clouds

Methods for processing point clouds/jets should respect the appropriate symmetries

Variable constituent multiplicity requires at least one of:

- Preprocessing to another representation (jet images, N-subjettiness, etc.)
- Truncation to an (arbitrary) fixed size
- Recurrent NN structure

Particle permutation symmetry requires:

- Permutation symmetric observables
- Permutation symmetric architectures

Jet Representations \longleftrightarrow Analysis Tools

Two key choices when analyzing jets

How to represent the jet

- Single expert observable
- A few expert observables
- Many expert observables
- Jet images
- List of particles
- Clustering tree
- N -subjettiness basis
- Energy flow polynomials
- Set of particles

How to analyze that representation

- Threshold cut
- Multidimensional likelihood
- Boosted decision tree (BDT), shallow neural network (NN)
- Convolutional NN (CNN)
- Recurrent/Recursive NN (RNN)
- Fancy RNN
- Dense neural network (DNN)
- Linear classification
- Energy flow network

Deep Sets Theorem [63]. Let $\mathfrak{X} \subset \mathbb{R}^d$ be compact, $X \subset 2^{\mathfrak{X}}$ be the space of sets with bounded cardinality of elements in \mathfrak{X} , and $Y \subset \mathbb{R}$ be a bounded interval. Consider a continuous function $f : X \rightarrow Y$ that is invariant under permutations of its inputs, i.e. $f(x_1, \dots, x_M) = f(x_{\pi(1)}, \dots, x_{\pi(M)})$ for all $x_i \in \mathfrak{X}$ and $\pi \in S_M$. Then there exists a sufficiently large integer ℓ and continuous functions $\Phi : \mathfrak{X} \rightarrow \mathbb{R}^\ell$, $F : \mathbb{R}^\ell \rightarrow Y$ such that the following holds to an arbitrarily good approximation:¹

$$f(\{x_1, \dots, x_M\}) = F \left(\sum_{i=1}^M \Phi(x_i) \right)$$

Particle Flow Network (PFN)

$$\text{PFN}(\{p_1^\mu, \dots, p_M^\mu\}) = F \left(\sum_{i=1}^M \Phi(p_i^\mu) \right)$$

Fully general latent space

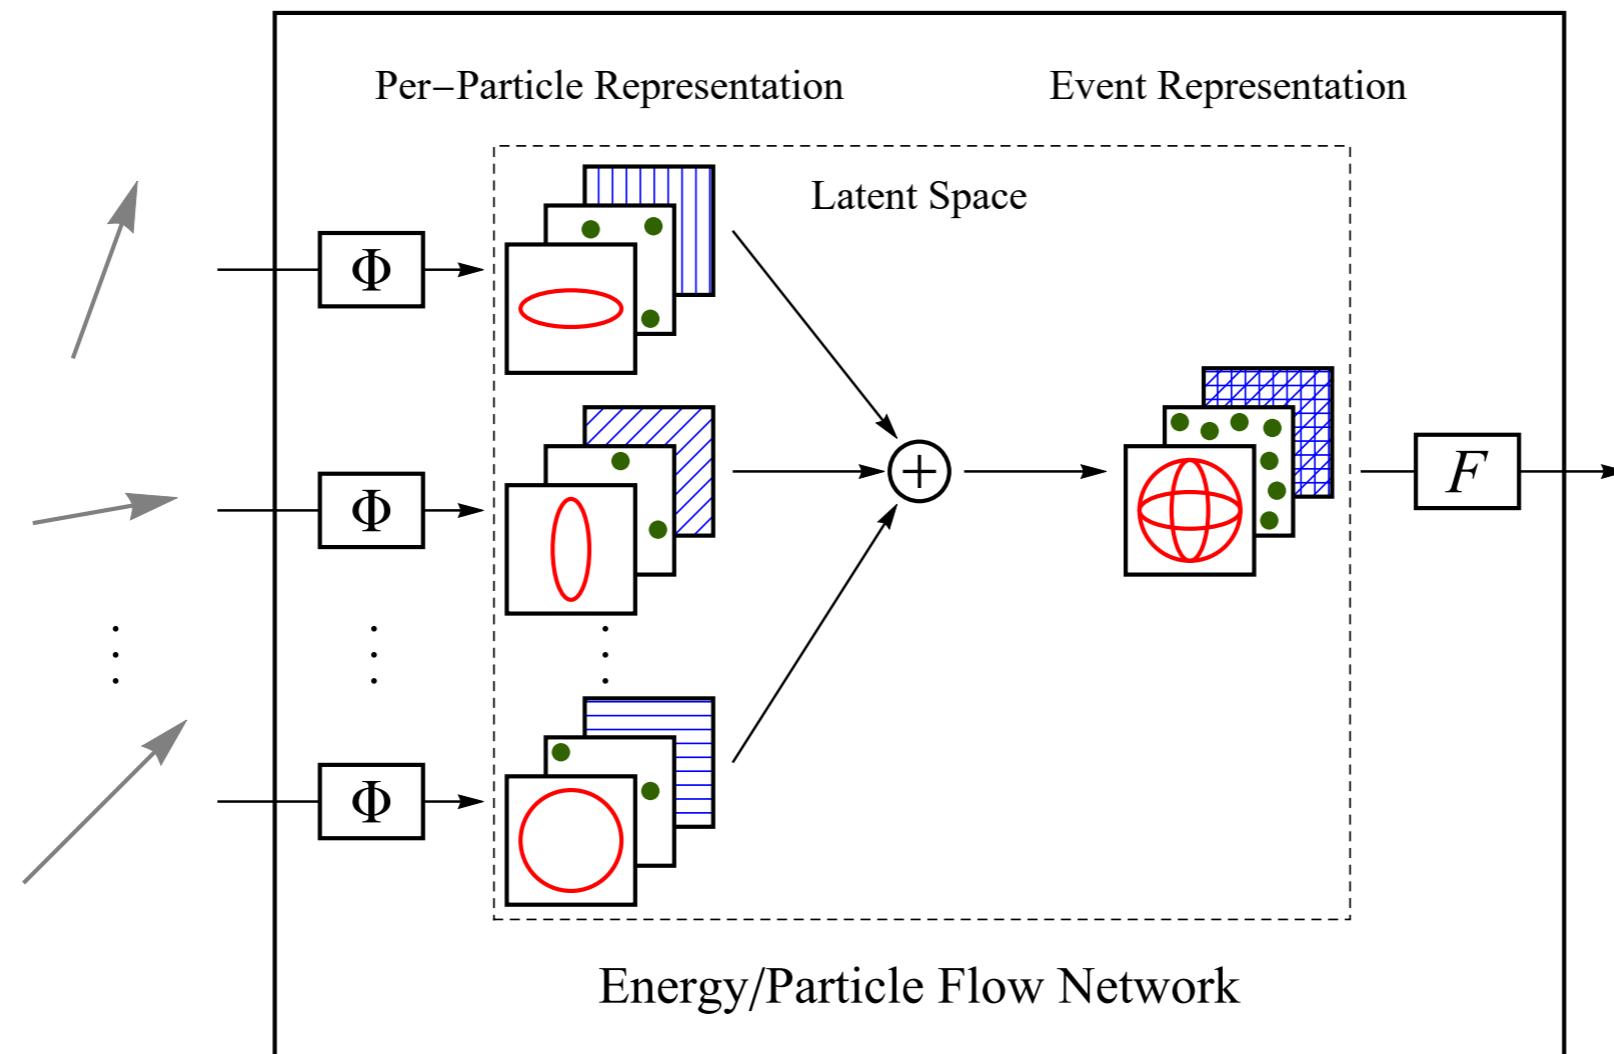

Energy Flow Network (EFN)

$$\text{EFN}(\{p_1^\mu, \dots, p_M^\mu\}) = F \left(\sum_{i=1}^M z_i \Phi(\hat{p}_i) \right)$$

IRC-safe latent space

Particles

Observable

Latent Space IRC Safety

Latent space defines new physics observables

IRC safety is a key theoretical *and experimental* property of observables

QCD has soft and collinear divergences associated with gluon radiation

$$dP_{i \rightarrow ig} \simeq \frac{2\alpha_s}{\pi} C_a \frac{d\theta}{\theta} \frac{dz}{z} \quad \begin{aligned} C_q &= C_F = 4/3 \\ C_g &= C_A = 3 \end{aligned}$$

Infrared (IR) safety – observable is unchanged under addition of a soft particle

$$S(\{p_1^\mu, \dots, p_M^\mu\}) = \lim_{\epsilon \rightarrow 0} S(\{p_1^\mu, \dots, p_M^\mu, p_{M+1}^\mu\}), \quad \forall p_{M+1}^\mu$$

Collinear (C) safety – observable is unchanged under a collinear splitting of a particle

$$S(\{p_1^\mu, \dots, p_M^\mu\}) = S(\{p_1^\mu, \dots, (1-\lambda)p_M^\mu, \lambda p_{M+1}^\mu\}), \quad \forall \lambda \in [0, 1]$$

Latent Space IRC Safety

Latent

IRC safe

QCD

Infrared

Collinear

IRC safety is a statement of *linearity* in energy and
continuity in geometry

Theorem: A generic function of four-momenta can be made IRC safe via the following replacement:

$$\sum_{i=1}^M f(p_i^\mu) \rightarrow \sum_{i=1}^M z_i f(\hat{p}_i).$$

Proof: In [I810.05165](#).

□

$$S(\{p_1^\mu, \dots, p_M^\mu\}) = S(\{p_1^\mu, \dots, (1 - \lambda)p_M^\mu, \lambda p_{M+1}^\mu\}), \quad \forall \lambda \in [0, 1]$$

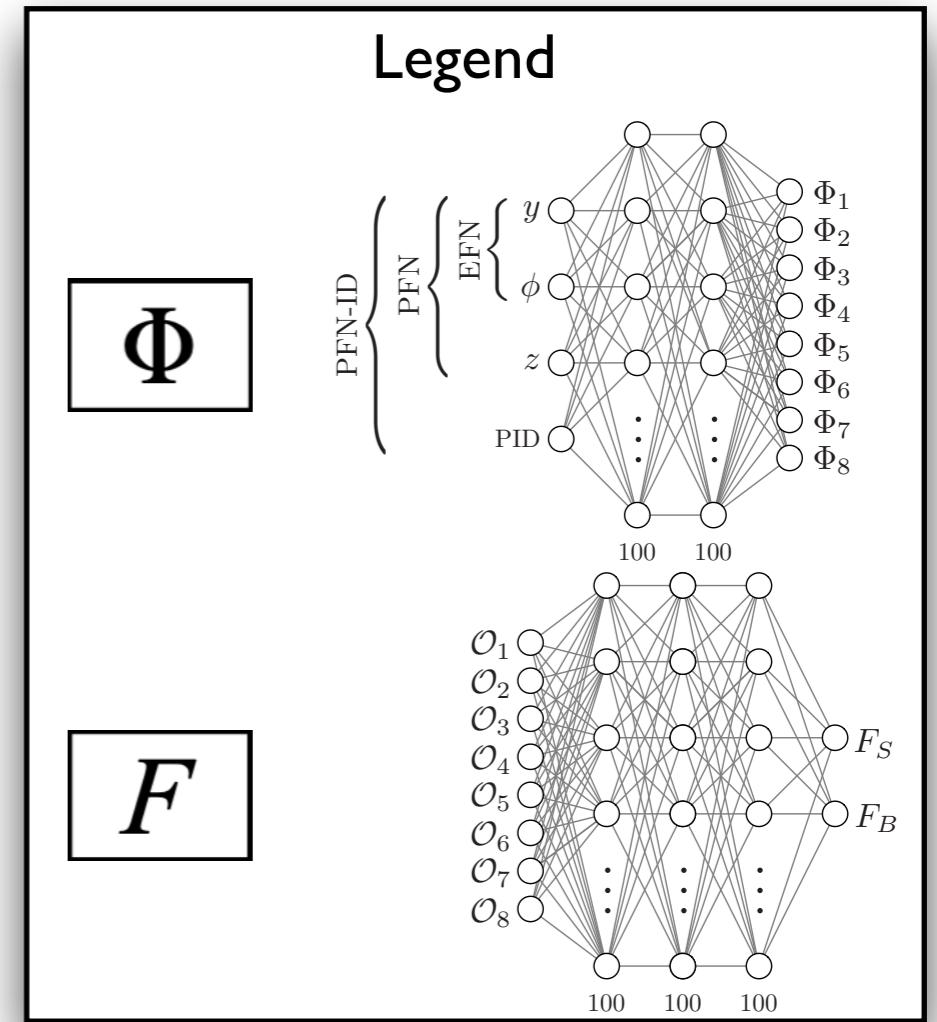

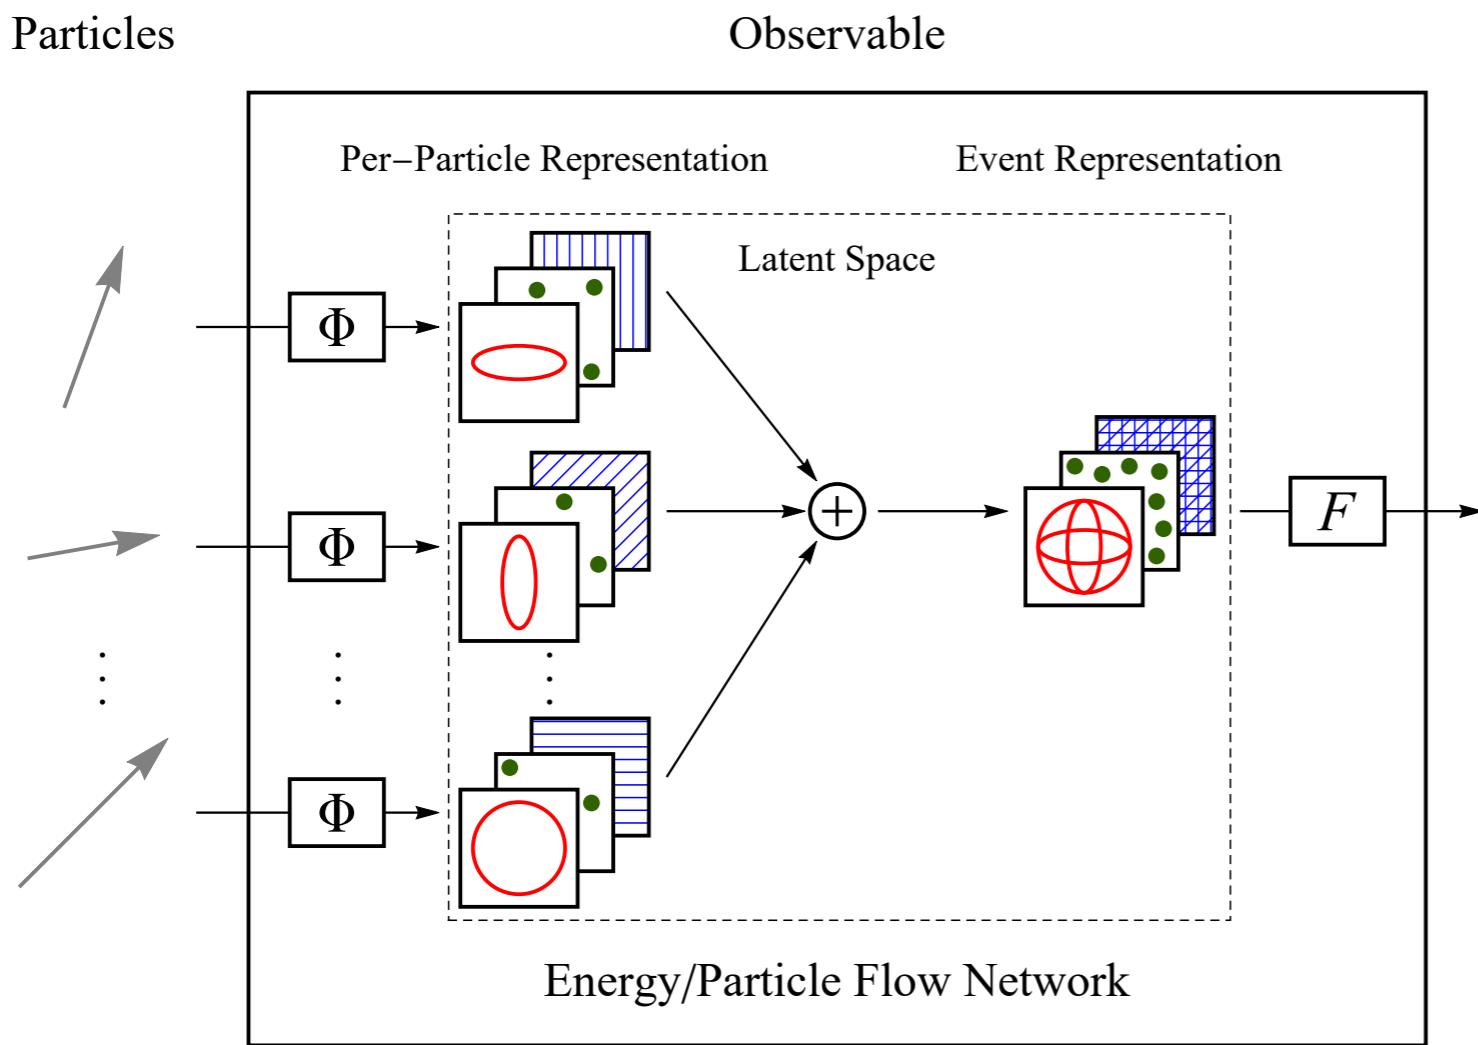

Approximating Φ and F with Neural Networks

Employ neural networks as arbitrary function approximators

Use fully-connected networks for simplicity

Default sizes – $\Phi: (100, 100, \ell)$, $F: (100, 100, 100)$

Particles

$$\text{EFN} : \mathcal{O}_a = \sum_{i=1}^M \textcolor{brown}{z}_i \Phi_a(\textcolor{violet}{y}_i, \phi_i)$$

$$\text{PFN} : \mathcal{O}_a = \sum_{i=1}^M \Phi_a(z_i, y_i, \phi_i, [\text{PID}_i])$$

Quantifying a Classifier

Receiver Operating Characteristic (**ROC**) curve:
True negative rate of the classifier at different true positive rates

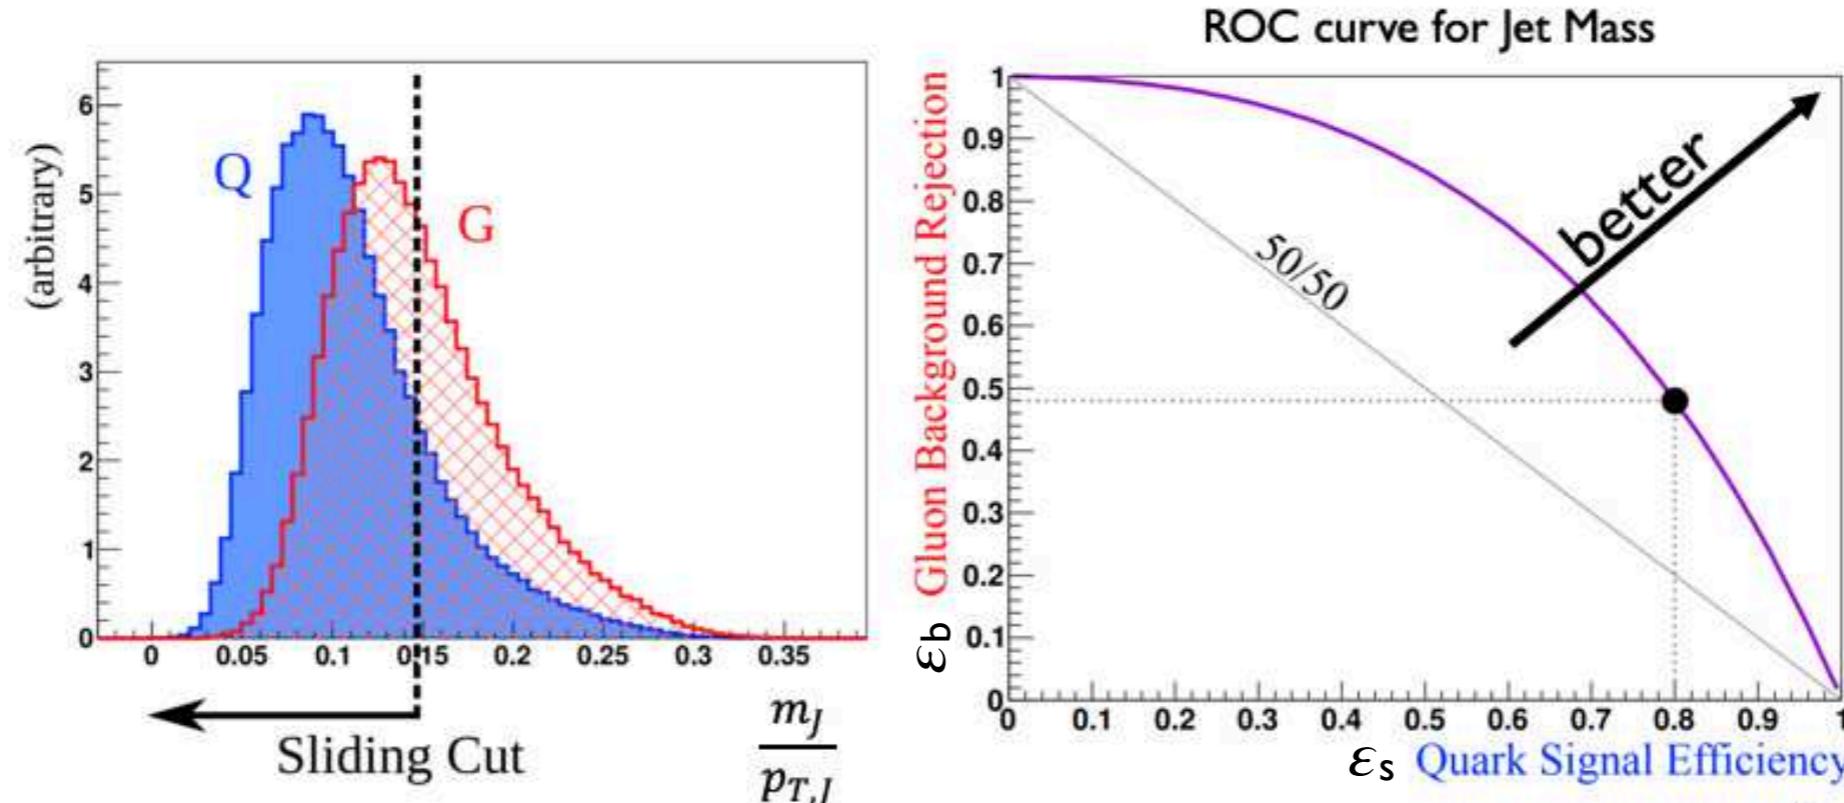

Figure from [1211.7038](#)

Area Under the ROC Curve (**AUC**) captures the classifier performance in a number.

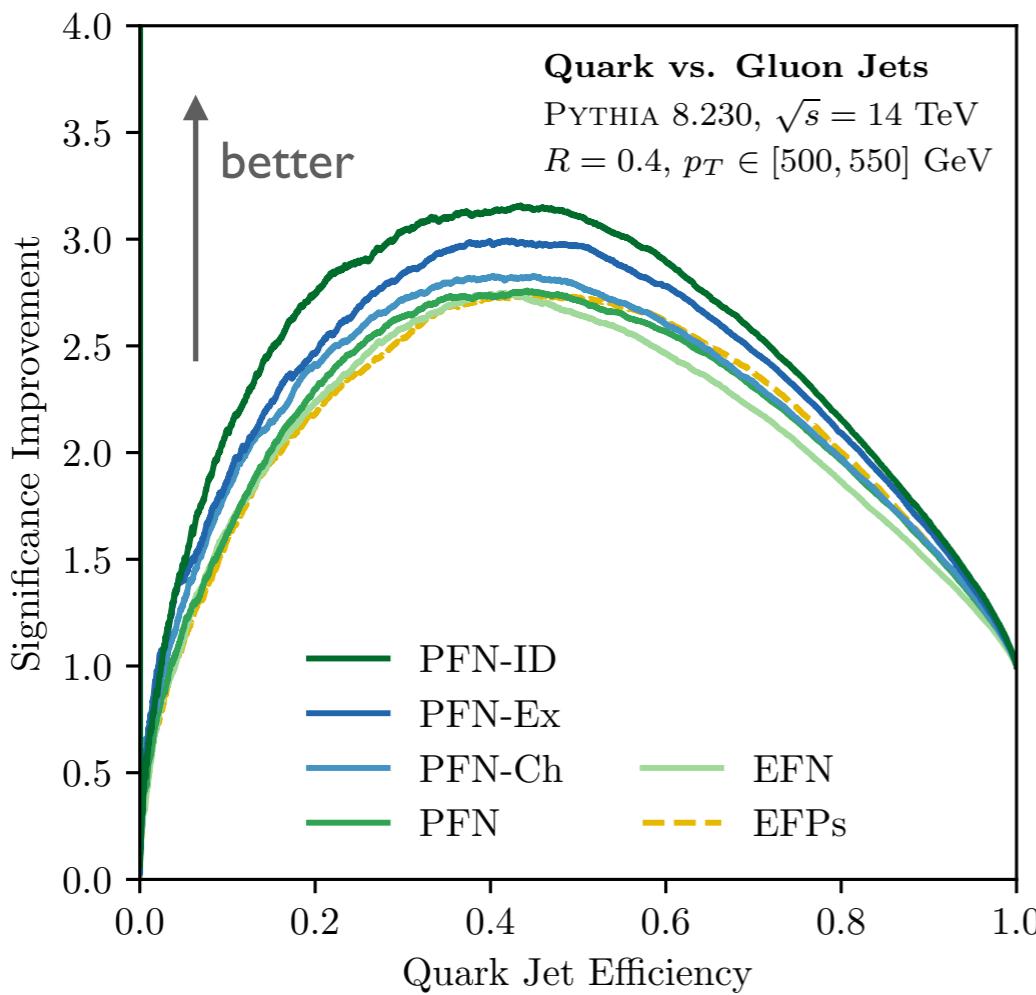

Other formats possible, e.g. $(\varepsilon_s, 1/(1 - \varepsilon_b))$, $(\varepsilon_s, \varepsilon_s/\sqrt{1 - \varepsilon_b})$

Classification Performance

PFN-ID: Full particle flavor info
 $(\gamma, \pi^\pm, K^\pm, K_L, p, \bar{p}, n, \bar{n}, e^\pm, \mu^\pm)$

PFN-Ex: Experimentally accessible info
 $(\gamma, h^{\pm,0}, e^\pm, \mu^\pm)$

PFN-Ch: Particle charge info
 $(+, 0, -)$

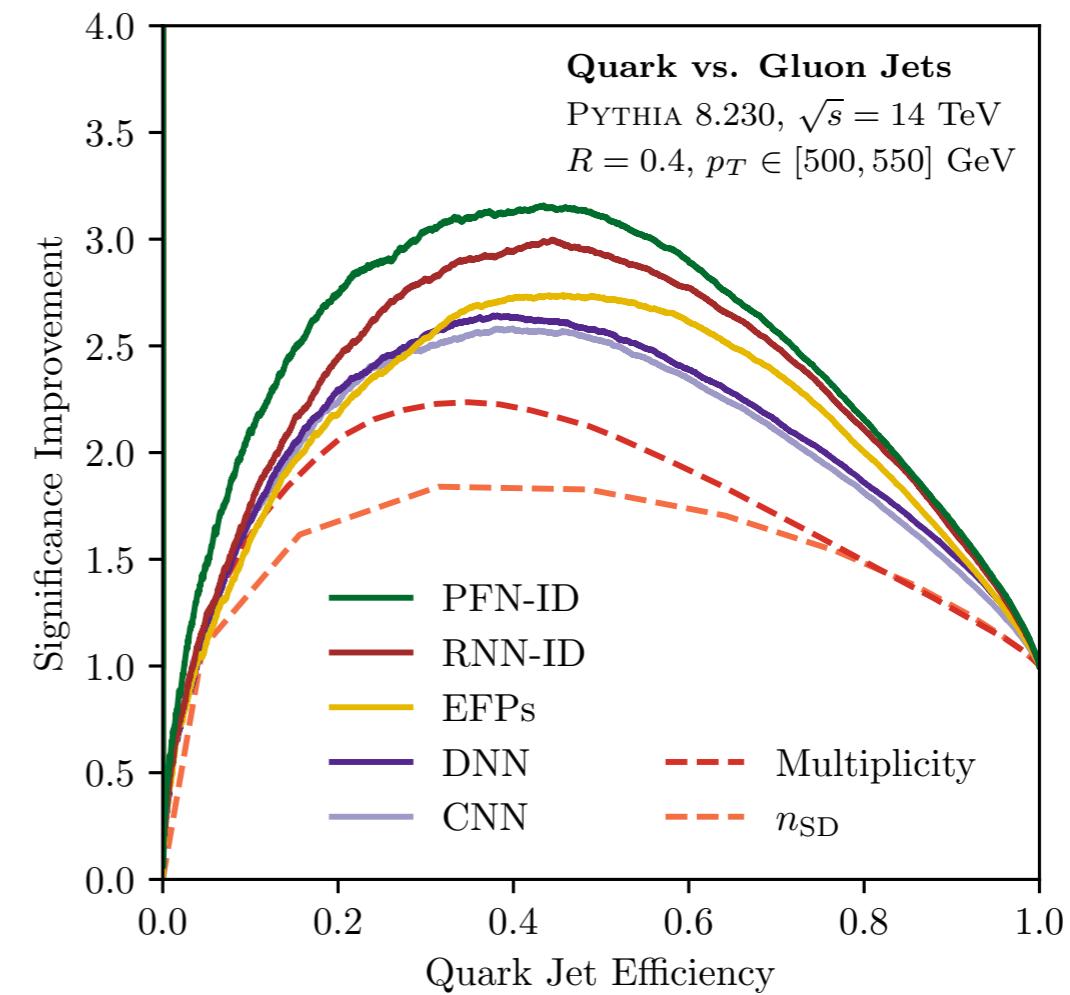

Latent space dimension $\ell = 256$

EFPs are comparable to EFN

PFN: No particle type info, arbitrary energy dependence

EFN: **IRC**-safe latent space

PFN-ID slightly better than RNN-ID

EFN Latent Dimension Sweep

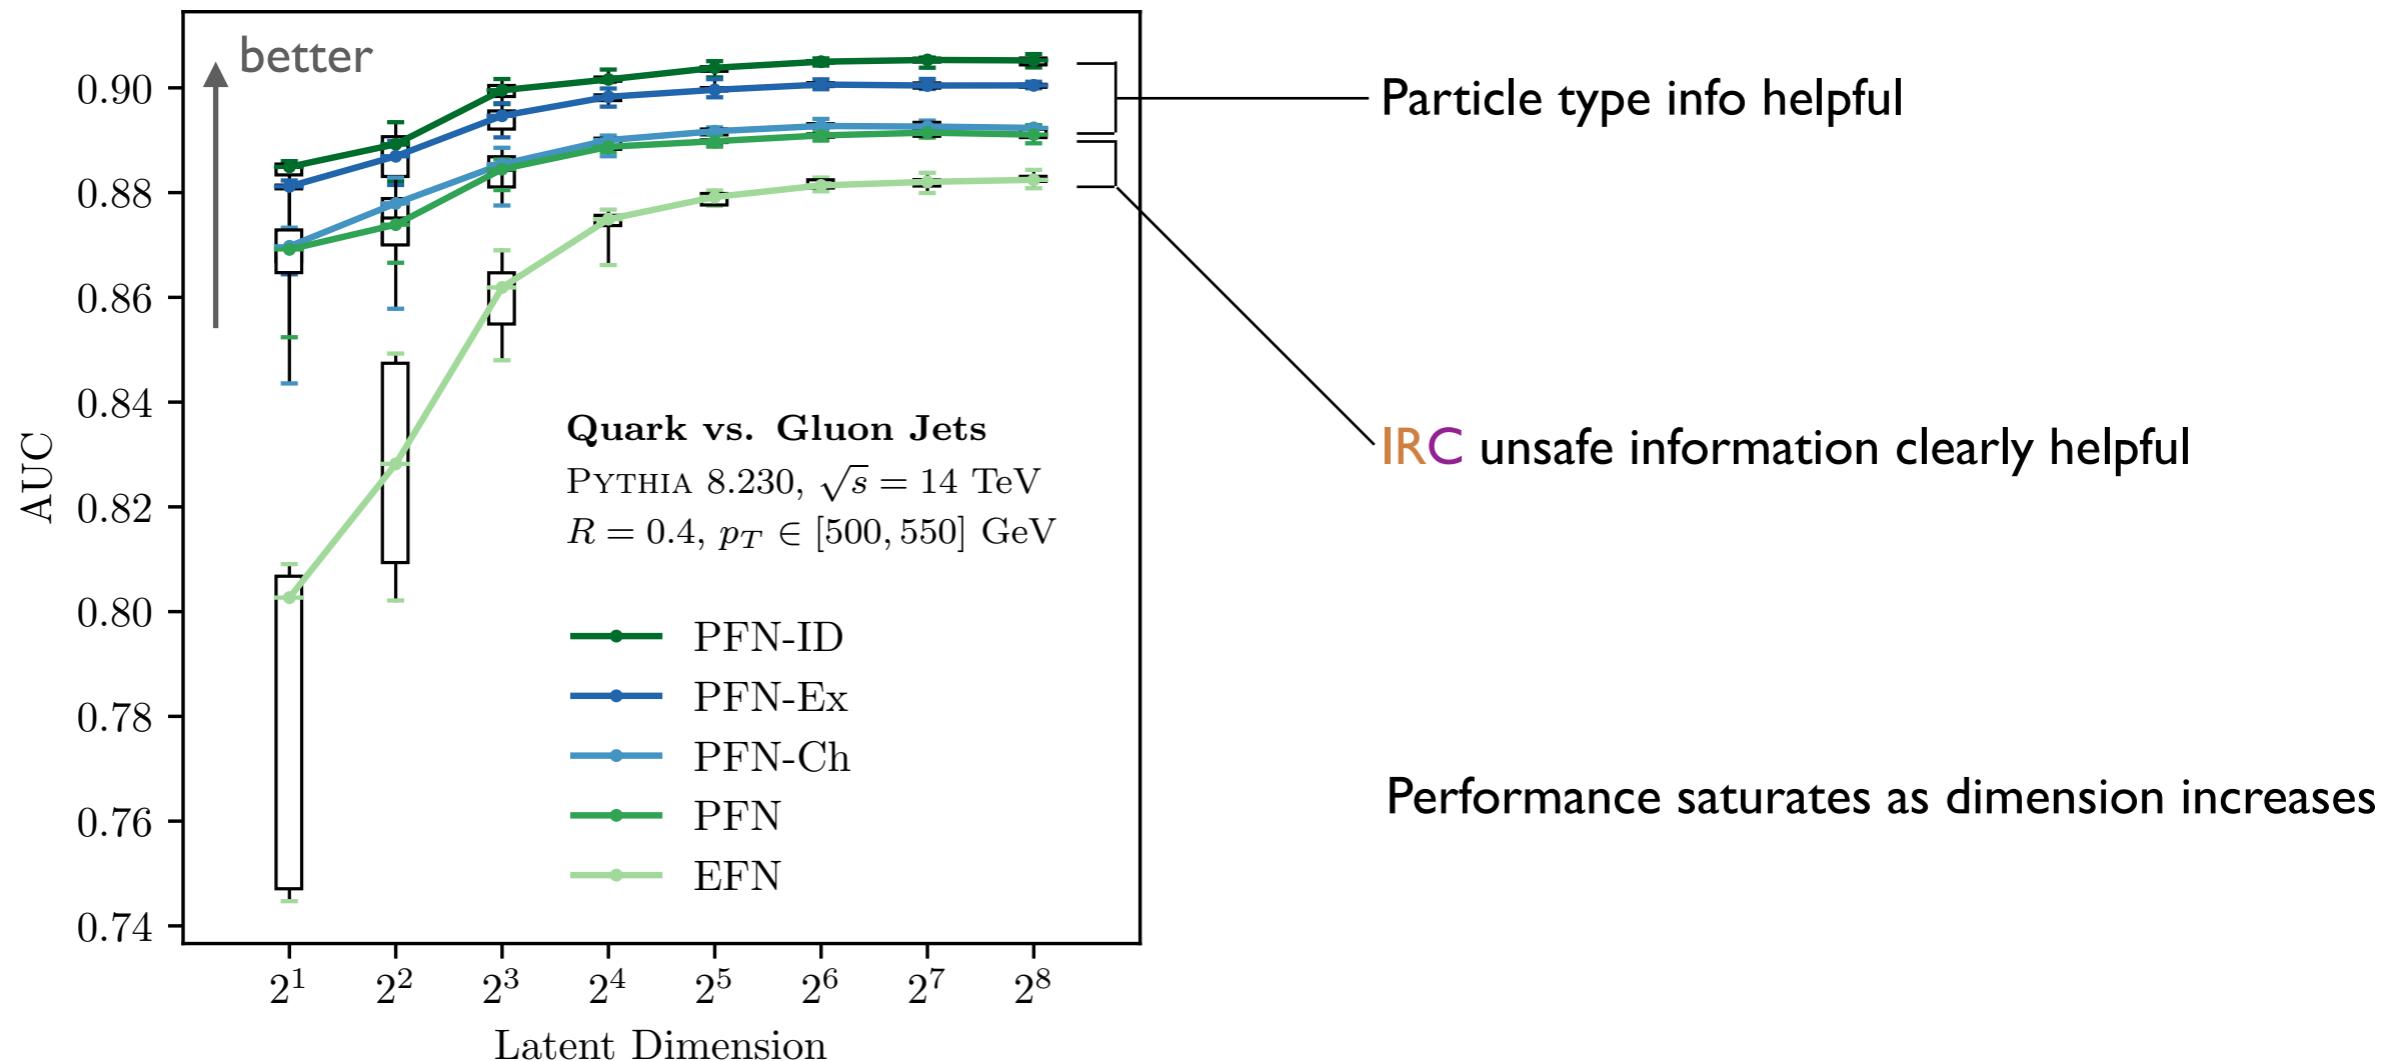

PFN-ID: Full particle flavor info
 $(\gamma, \pi^\pm, K^\pm, K_L, p, \bar{p}, n, \bar{n}, e^\pm, \mu^\pm)$

Extracting New Analytic Observables

$$\mathcal{O}_1 = \sum_{i=1}^M z_i \Phi_1(\theta_i)$$

$$\mathcal{O}_2 = \sum_{i=1}^M z_i \Phi_2(\theta_i)$$

Take radial slices to obtain envelope

EFN ($\ell = 2$) has approximately radially symmetric filters

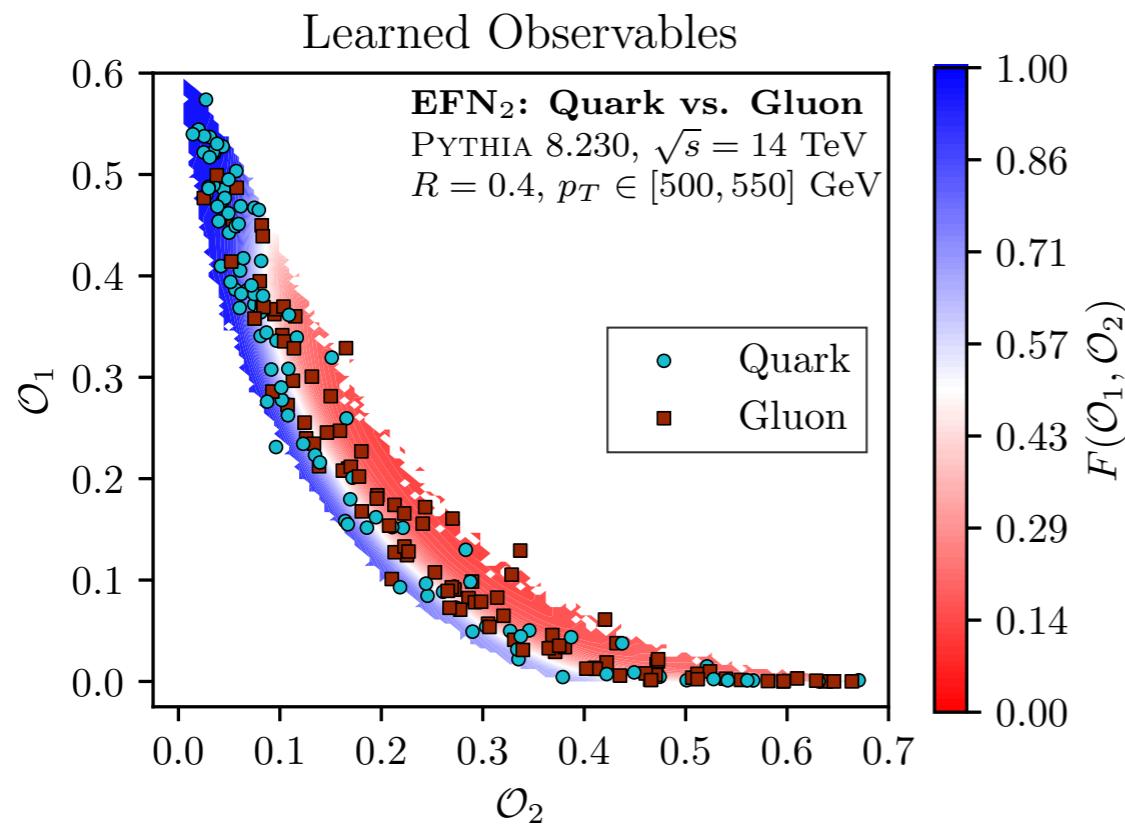

Fit functions of the forms:

$$A_{r_0} = \sum_{i=1}^M z_i e^{-\theta_i^2/r_0^2}, \quad B_{r_1, \beta} = \sum_{i=1}^M z_i \ln(1 + \beta(\theta_i - r_1)) \Theta(\theta_i - r_1)$$

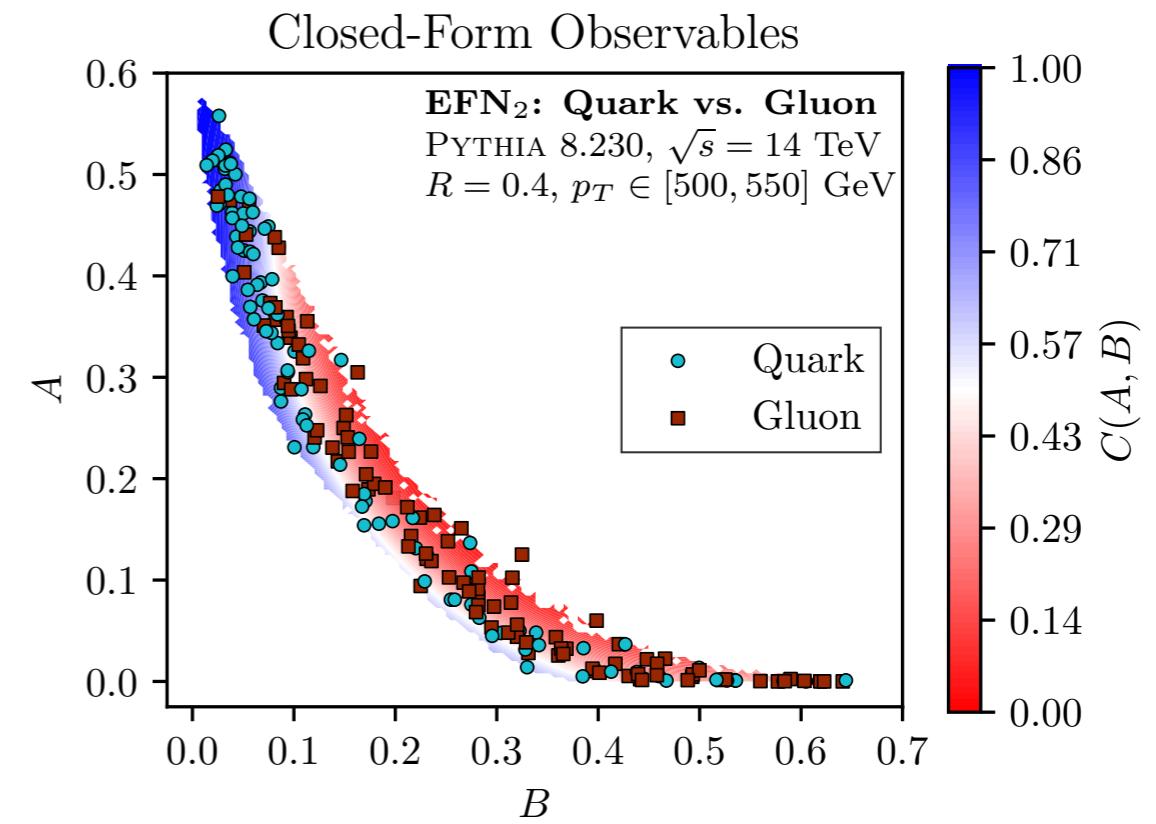

Separate soft and collinear phase space regions

Extracting New Analytic Observables

Can visualize F in the two dimensional $(\mathcal{O}_1, \mathcal{O}_2)$ phase space

Learned

Extracted

Extract analytic form for F as (squared) distance from a point:

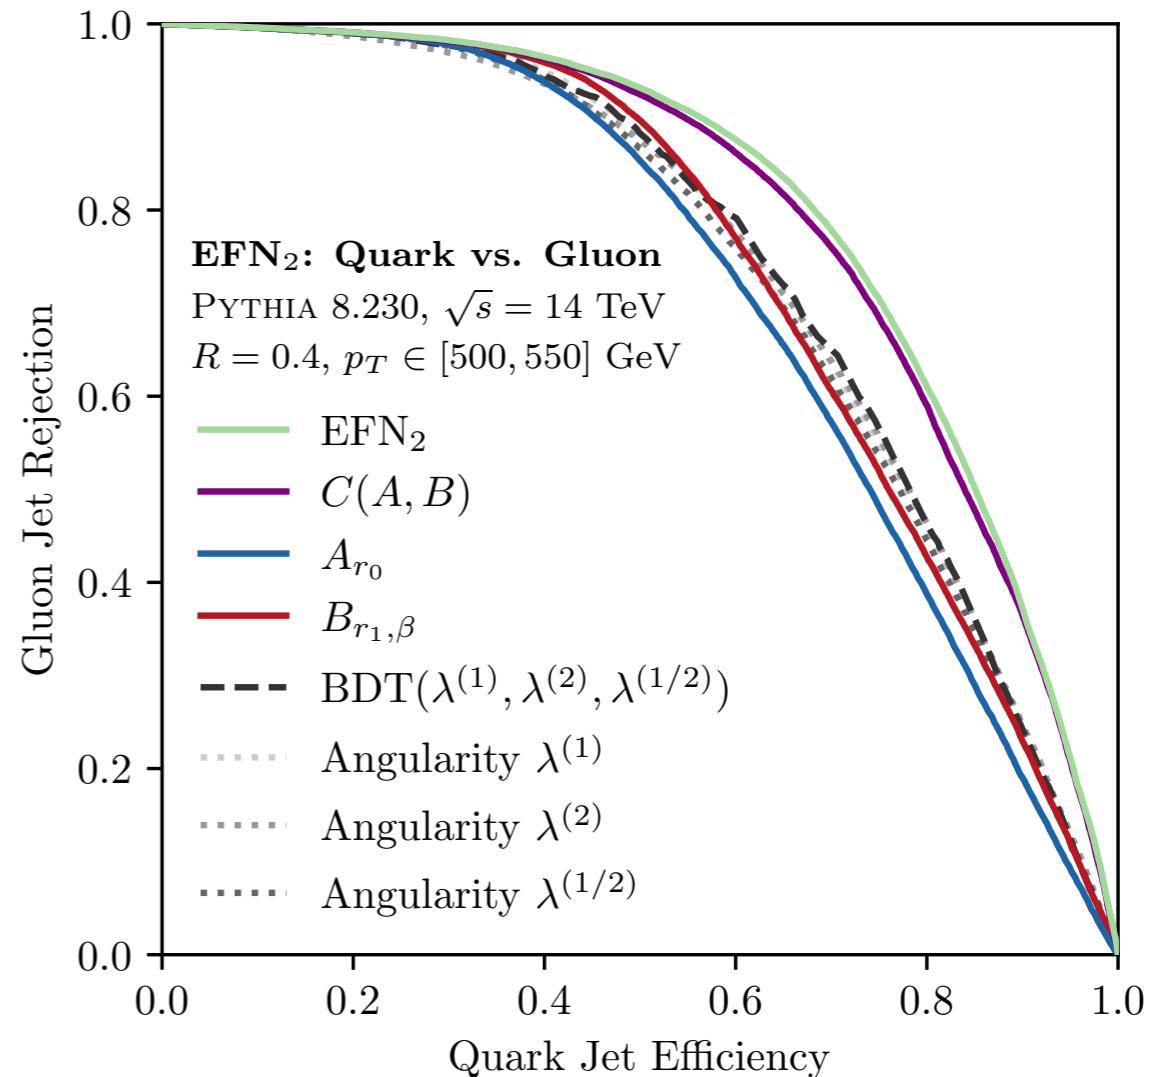

$$C(A, B) = (A - a_0)^2 + (B - b_0)^2$$

Benchmarking New Analytic Observables

Individually, extracted observables are comparable to other angularities

Extracted $C(A, B)$ performs nearly as well as EFN ($\ell = 2$)

Meanwhile, multivariate combination (BDT) of three other angularities does not show improvement

Top Jet Samples and Other Methods

Below this is a search bar labeled "Search docs". The sidebar menu includes links for "Home", "Welcome to EnergyFlow", "References", "Copyright", "Getting Started", "Installation", "Demo", "Examples", "FAQs", "Documentation", "Energy Flow Polynomials", "Architectures", "Measures", "Generation", "Utils", and "Datasets". The main content area has a header "Welcome to EnergyFlow" and a sub-header "Docs » Home". The text describes EnergyFlow as a Python package for computing Energy Flow Polynomials (EFPs) and implementing Energy Flow Networks (EFNs) and Particle Flow Networks (PFNs). It lists several features: EFPs, EFNs, PFNs, jet tagging datasets, additional architectures, and detailed examples. The "Architectures" section is currently selected, indicated by a dark grey background.

Docs » Home

Welcome to EnergyFlow

EnergyFlow is a Python package for a suite of particle physics tools for computing Energy Flow Polynomials (EFPs) and implementing Energy Flow Networks (EFNs) and Particle Flow Networks (PFNs). Here are several of the features and functionalities provided by the EnergyFlow package:

- [Energy Flow Polynomials](#): EFPs are a collection of jet substructure observables which form a complete linear basis of IRC-safe observables. EnergyFlow provides tools to compute EFPs on events for several energy and angular measures as well as custom measures.
- [Energy Flow Networks](#): EFNs are infrared- and collinear-safe models designed for learning from collider events as unordered, variable-length sets of particles. EnergyFlow contains customizable Keras implementations of EFNs.
- [Particle Flow Networks](#): PFNs are general models designed for learning from collider events as unordered, variable-length sets of particles, based on the [Deep Sets](#) framework. EnergyFlow contains customizable Keras implementations of PFNs.

Beyond the primary functions described above, the EnergyFlow package also provides useful supplementary features. These include a large quark/gluon jet dataset, implementations of additional machine learning architectures useful for collider physics, and many examples exhibiting the usage of the package.

- [Jet Tagging Datasets](#): A dataset of 2 million simulated quark and gluon jets is provided.
- [Additional Architectures](#): Implementations of other architectures useful for particle physics are also provided, such as convolutional neural networks (CNNs) for jet images.
- [Detailed Examples](#): Examples showcasing EFPs, EFNs, PFNs, and more. Also see the [EFP Demo](#).

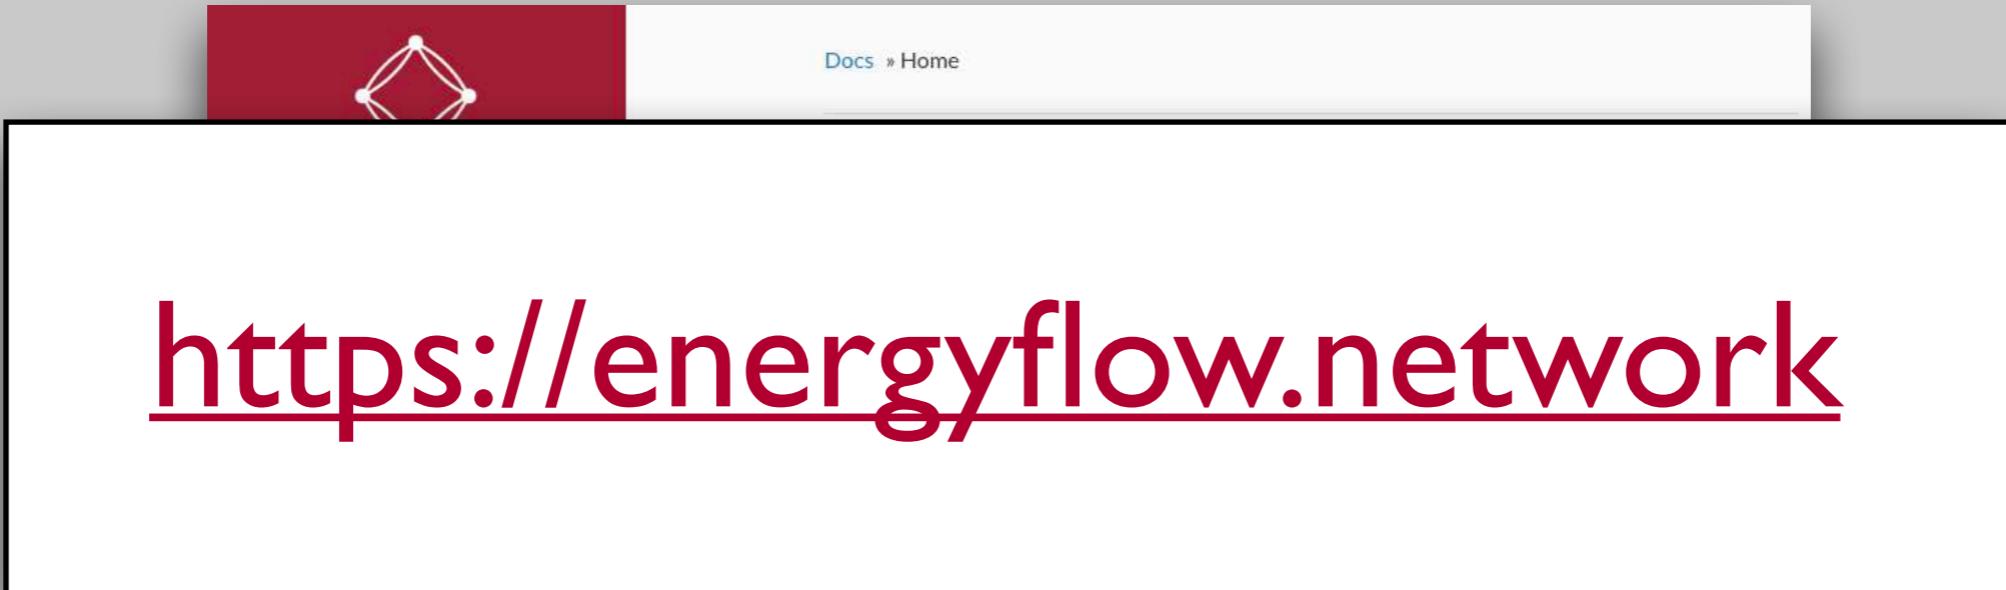

EnergyFlow Python Package

Contains EFN and PFN implementations in Keras

CNN, DNN architectures included
for easy model comparison

Includes quark/gluon jet samples used in [1810.01565]

Several detailed examples demonstrating how to train models and make visualizations

The screenshot shows the homepage of the EnergyFlow network documentation. At the top, there is a red header bar with a logo and navigation links for 'Docs' and 'Home'. Below the header, the main title 'https://energyflow.network' is displayed prominently in large red text. On the left side, there is a dark sidebar containing links to various documentation sections: Examples, FAQs, Documentation, Energy Flow Polynomials, Architectures, Measures, Generation, Utils, and Datasets. The main content area contains several bullet points describing the package's features:

- **Particle Flow Networks:** PFNs are general models designed for learning from collider events as unordered, variable-length sets of particles, based on the Deep Sets framework. EnergyFlow contains customizable Keras implementations of PFNs.
- **Beyond the primary functions described above,** the EnergyFlow package also provides useful supplementary features. These include a large quark/gluon jet dataset, implementations of additional machine learning architectures useful for collider physics, and many examples exhibiting the usage of the package.
- **Jet Tagging Datasets:** A dataset of 2 million simulated quark and gluon jets is provided.
- **Additional Architectures:** Implementations of other architectures useful for particle physics are also provided, such as convolutional neural networks (CNNs) for jet images.
- **Detailed Examples:** Examples showcasing EFPs, EFNs, PFNs, and more. Also see the [EFP Demo](#).

Thank You!

Computation Complexity of EFPs – Variable Elimination

Naive computation complexity of an energy correlator is $\mathcal{O}(M^N)$

For ~ 100 particles this becomes intractable for $N > 4$

Computation Complexity of EFPs – Variable Elimination

Naive computation complexity of an energy correlator is $\mathcal{O}(M^N)$

For ~ 100 particles this becomes intractable for $N > 4$

EnergyCorrelator fjcontrib package gives up in this case

```
// if N > 5, then throw error
if (_N > 5) {
    throw Error("EnergyCorrelator is only hard coded for N = 0,1,2,3,4,5");
}
```

Computation Complexity of EFPs – Variable Elimination

Naive computation complexity of an energy correlator is $\mathcal{O}(M^N)$

For ~ 100 particles this becomes intractable for $N > 4$

→ EnergyCorrelator fjcontrib package gives up in this case

```
// if N > 5, then throw error
if (_N > 5) {
    throw Error("EnergyCorrelator is only hard coded for N = 0,1,2,3,4,5");
```

Variable elimination (VE) algorithm can speedup EFPs by finding efficient elimination ordering

$$= \left(\sum_{i_1=1}^M \sum_{i_2=1}^M \sum_{i_3=1}^M z_{i_1} z_{i_2} z_{i_3} \theta_{i_1 i_2}^2 \theta_{i_2 i_3} \right) \left(\sum_{i_4=1}^M \sum_{i_5=1}^M z_{i_4} z_{i_5} \theta_{i_4 i_5}^4 \right)$$

Disconnected is product of connected

$$\begin{aligned} &= \underbrace{\sum_{i_1=1}^M \sum_{i_2=1}^M \sum_{i_3=1}^M \sum_{i_4=1}^M \sum_{i_5=1}^M \sum_{i_6=1}^M \sum_{i_7=1}^M \sum_{i_8=1}^M z_{i_1} z_{i_2} z_{i_3} z_{i_4} z_{i_5} z_{i_6} z_{i_7} z_{i_8}}_{\mathcal{O}(M^8)} \prod_{j=2}^7 \theta_{i_1 i_j} \\ &= \underbrace{\sum_{i_1=1}^M z_{i_1} \left(\sum_{i_2=1}^M z_{i_2} \theta_{i_1 i_2} \right)^7}_{\mathcal{O}(M^2)} \end{aligned}$$

Clever parentheses placement corresponds to good elimination ordering

All tree graphs become $\mathcal{O}(M^2)$
